

DM Ads Attribution

Real ROAS for DM funnels, per ad, updating on its own.

Why DM ads are different

If you were running a normal funnel, Ads Manager would show you the conversion. Someone clicks, they hit a landing page, the pixel fires, and Facebook tells you which ad made the sale.

DM ads do not work like that. The conversation happens inside Instagram. Facebook never sees the booking, never sees the call, and never sees the money. So the column you actually care about — **which ad produced buyers** — does not exist in Ads Manager, and never will.

And the number it does give you is wrong

Facebook reports a cost per DM. That number is consistently optimistic — it counts conversations started far more generously than you would. So the one metric you are handed is inflated, and you are making budget decisions on it.

Which leaves you doing it by hand

Most people running DM ads end up somewhere like this:

- a spreadsheet that gets rebuilt every time you launch a new campaign
- setters logging things manually, every day, and forgetting some of them
- spend in one place, DMs in another, bookings in a third, cash in a fourth
- a monthly total that is roughly right, and no idea which ad produced it

It is not that you are bad at tracking. It is that nothing was built to track this.

So I built it

This is the attribution system I use for my own DM ads, and it is what this document sets up for you, in your own business, on your own accounts.

It follows one person the whole way through, and the connection holds the entire time:

they see your ad	
they DM you the word	-> a DM
they book a call	-> a booking
they show up	-> a call taken
they pay you	-> a sale

Then it adds it up per ad. Not per campaign. Per ad.

So instead of "we spent \$4,000 and made \$11,000", you get one row per ad telling you that *this* one costs \$9 a DM and has made three sales, and *that* one has spent \$600 and produced nothing.

What changes day to day. Once it is set up, every campaign and every ad set you launch from then on is tracked automatically. Nobody logs anything. You are not chasing setters for numbers. You open one page and the real cost per DM, cost per booked call, show rate and ROAS are already sitting there, updated within the hour.

PART ONE

How the connection actually holds

Worth understanding, because two of the pieces are things only you can do.

The keyword is the tracking number. Your ad tells someone to send a word. That same word travels the whole way down the funnel:

Where	What carries the keyword
The ad	the ad's name in Ads Manager
The DM	what they actually typed, captured by ManyChat
The booking	the booking link your setter sends, which carries the keyword in it
The sale	the ManyChat link pasted on the row in your sales tracker

Four links in a chain. Break any one and the rest of that person's journey goes dark — not wrong, just unknown, which the dashboard will show you honestly.

The middle two are automatic once set up. The first and last are on you.

It will not guess

If it cannot prove a sale came from a particular ad, it shows as **unattributed** rather than being quietly assigned to whichever ad looks likeliest.

This is on purpose, and it is the reason the numbers are worth anything. Money you can see is unaccounted for is a problem you can go and fix. Money silently credited to the wrong ad is a decision you will get wrong and never find out about.

Hover any number and it shows you what it was built from.

PART TWO

The two things only you can do

Everything else in this document gets done for you. These two do not, and if you skip them the dashboard will be empty and you will think it is broken.

1. Name your ads after the keyword

Whatever word your ad tells people to send — that is the ad's name in Ads Manager.

Your ad says	Name the ad
DM me TRIM	TRIM
DM me MIGHTY	MIGHTY
DM me TEMPO	TEMPO

That is it. Plain. The keyword and nothing else is the cleanest way to do it, and it is how I name mine.

If you want other things in the ad name too, that is fine — but the keyword has to be the LAST word. The system reads the last word of the name. So Lead Magnet | TRIM works and gives you *trim*. TRIM retarget does not — it reads as *retarget*, and that ad will never be credited with anything. If you are not sure, just name it the keyword.

An ad named wrong is not broken. It still shows up, still shows its spend, and sits there with zeros beside it, because nothing can honestly tie a DM to it.

2. Never run the same word twice at once

One live ad, one word. If two ads both say *DM me TRIM* and someone DMs TRIM and buys, nothing on earth can tell you which ad did it.

Reusing a word later is fine. Leave a few weeks after turning the first one off, so a late DM from the old ad does not get credited to the new one.

PART TWO

Your sales tracker

Your sales tracker is where the money lives, so it is what turns this from a funnel counter into actual ROAS. You are going to connect it to the system, and it stays exactly where it is — you keep working in the same sheet you already use.

This system can only read your sheet. It can never write to it, change it, or reorganise it. It also never converts your money between currencies — what you typed is what it shows.

The columns it reads

You almost certainly have most of these already. The column letters do not matter and the names do not matter — you say which is which during setup, once.

Column	Why it is needed
Date	which day the call belongs to. Required.
Name	who it was. Required.
ManyChat link	the important one. Ties the sale back to the DM, and therefore to the ad
Did they show	your show rate, and it separates a no-show from a lost sale
Cash collected	the money. This is what ROAS is calculated on
Total contracted	the full deal value, for when it differs from cash in hand
Outcome	won, lost, no-show, follow-up
Closer	who took it
Setter	who set it

Add the ManyChat link column if you do not have it

When your setter books someone, they paste that person's ManyChat conversation link onto the row. It takes three seconds and it is the single highest-value habit in this whole system.

Without it, sales get matched to DMs by name alone. Two people called Sarah, someone using a nickname, a typo — and the match fails silently. With the link it is exact, every time.

One thing that stays a human job. Whoever takes the call fills in whether they showed and what they paid. Nothing can automate that, and the dashboard reads those two columns directly. Empty columns mean no show rate and no revenue — not a bug, just nothing to read.

PART THREE

Setting it up

Open Claude Code and paste in the link to the project. Tell it to install this.

It will ask you about your business — what you use for DMs, what you book calls with, and what the columns in your sales tracker are called — and then build the whole thing around your answers. You do not edit any files.

Roughly 45 minutes, and most of that is waiting for accounts to finish creating.

The four things to go and get

Claude cannot log into your accounts for you, so these four are yours. Collect them first and the rest goes quickly.

	What	Where	What it is for
1	Supabase token	supabase.com	Where your numbers get stored
2	Meta ad account id + token	business.facebook.com	Your ad spend
3	Vercel token	vercel.com	Puts it on the internet
4	Your sales tracker link	Google Sheets	Your money

1. Supabase — where the numbers live

A database is just the filing cabinet the numbers get kept in. Free at the size you need.

- 1 Go to **supabase.com** and make an account.
- 2 Go to **supabase.com/dashboard/account/tokens**
- 3 Click **Generate new token**. Name it anything.
- 4 Copy it and give it to Claude.

From that one token Claude creates the project and builds everything inside it. You never have to click around in Supabase.

2. Meta — your ad spend

Your ad account id is in **Ads Manager**, top left, next to the account name. It looks like `act_123456789`.

Then the access token. Use the kind that never expires — the normal kind dies after about two months and takes your dashboard down with no warning.

- 1 Go to **business.facebook.com** → **Business Settings**
- 2 Left menu: **Users** → **System Users**
- 3 **Add**. Name it anything. Role: **Admin**.
- 4 **Add Assets** → **Ad Accounts** → tick your ad account → turn on **Manage campaigns**
- 5 **Generate New Token**. Pick your app. Tick **ads_read** and **ads_management**. Expiry: **Never**.
- 6 Copy it. It is only shown once.

This is the fiddliest part of the whole setup. If you get lost, tell Claude which screen you are actually looking at and it will walk you through from there. Everything after this is easier.

3. Vercel — where the website lives

- 1 Go to **vercel.com** and make an account.
- 2 Go to **vercel.com/account/tokens**
- 3 Click **Create Token**. Name it anything.
- 4 Copy it and give it to Claude.

4. Your sales tracker

- 1 Open your sales tracker in Google Sheets.
- 2 Click **Share** → under **General access**, change **Restricted** to **Anyone with the link**. Leave it on **Viewer**.
- 3 Copy the link from your browser's address bar and give it to Claude.

That is the whole job. Claude reads your column names itself and tells you which column it thinks is which — you just confirm it got them right.

PART THREE

Connecting ManyChat

Two things happen here. The first is a small addition to the keyword automation you already have. The second is a new automation you build, which is what gets the keyword onto the booked call. Claude gives you the private address to paste in.

Where the keyword gets captured

In the automation that fires when someone sends one of your keywords, you add two things to the Actions block:

- **Set User Field** — save the keyword to a custom field, set to **Last Text Input**. This grabs whichever word they actually sent.
- **External Request** — the step that sends it over. Claude gives you the address and exactly what goes in it.

One automation covers all your keywords. Because the keyword is read from what they typed, you do not need a separate automation per word. List every keyword on the same trigger, and each DM records itself correctly. If you split conversations between setters with a randomiser, that keeps working exactly as it does now — put the request step after it, in the actions.

The booking automation you need to build

This one is new — you are creating it, not editing something you already have. It is what carries the keyword onto the booked call, and without it every booking arrives with no idea which ad caused it.

- 1 **Make a tag**, named after the calendar it sends. Something like 1_Day_Calendar. One tag per calendar you offer.
- 2 **Make an automation** triggered by **Contact event occurs** → **Tag applied**, set to that tag.
- 3 Its only step is **Send Message**, containing your booking link with the keyword on the end of it:

```
your-booking-link?utm_content={keyword}
```

Make sure the keyword shows up BLUE. Insert it using ManyChat's field picker, so it becomes the actual custom field. In the editor it appears as a blue chip. If it is plain black text, ManyChat will literally send the characters {keyword} to every lead and nothing will attribute. Blue means it works.

From then on your setter's entire job is: apply the tag. The calendar link goes out by itself, with that person's keyword already inside it.

If you offer more than one calendar, each tag needs its own automation, and every one of those links needs the keyword on it.

Your booking tool

Whatever fires when a call actually gets booked needs to send it over too. GoHighLevel, Calendly and most others can do this; the menus differ, so tell Claude which one you use and it will give you the exact steps.

Which calendars are sales calls

Claude asks you this during setup, so it is done before you ever open the dashboard. You just say which of your calendars are **sales calls** — not onboarding calls, not coaching calls. Those are real bookings, they are just not what you are measuring.

Later, once real bookings are flowing, Claude can list the calendars actually showing up in your data and check them against what you said. That catches the classic one: two calendars with nearly the same name, quietly splitting your bookings in half.

When it is done

You get your own web address, something like your -name.vercel.app, behind a password you picked. It works on your phone.

It updates itself every hour, whether your computer is on or not. From this point on, every new campaign and every new ad set you launch is tracked from the moment it goes live — as long as the ad name ends in its keyword.

Check these four before you call it finished

Check

- Your ad spend is showing
 - Send yourself a test DM with one of your keywords — it lands in the DM column
 - Book a test call — it lands in the booked column
 - Ask Claude to run the setup check, and it comes back clean
-

If any is zero, tell Claude. A setup that finished but shows an empty table is not finished, and you will not notice for a week.

If something looks off later

Tell Claude what you are seeing in your own words. There is a check built in that finds most of it.

The usual suspects:

What you see	What it usually is
One ad shows spend and nothing else	Its name does not end in its keyword
Spend, but no DMs at all	The ManyChat request step is not firing
DMs, but no booked calls	Your sales calendars have not been marked yet
Booked calls look too low	Two calendars with nearly the same name, splitting your bookings
Bookings show, but no keyword	The booking link is missing utm_content
Sales show as unattributed	No ManyChat link on those rows in your tracker

The whole thing in one line: the keyword goes at the end of the ad name, rides the booking link, and lands on the sales row. Claude does the rest.
